Designing Your AAA Sequence

Workbook Section Two | Questions 7-12

Project: CS110 Study Task Hub
Route: Operations Hub

Design plan: proposed behavior and peer checks are not recorded test results.

Stage 1: Application

7. What will the learner try immediately?

The learner types a study task, such as Finish CS110 whiteboard, and clicks Add. The task appears in the list with a visible confirmation.

8. What productive friction should fail safely?

The learner tries adding an empty entry or only spaces. The app rejects it without crashing and asks for a task name. The learner can correct the input and try again.

Stage 2: Action

9. Which core concepts follow the first attempt?

XAML controls; Click events and C# handlers; methods and scope; input validation; and ObservableCollection with ItemsSource binding.

10. How will the learner refine the initial work?

The learner traces Add_Click to AddItem, uses Trim and a blank-input check, and improves labels and status messages. A peer test will check whether the first action is clear.

Stage 3: Amplification

11. What broader practices become available?

Peer usability testing, GitHub checkpoints, and reusable event and validation patterns. The same structure can support an inventory list or a team task tracker.

12. How does AAA work at macro and micro scales?

For the full project: try a task workflow, learn its event and data structure, then extend it with a timer and text report. For one action: try Add, explain how it works, then adapt the validation pattern for Remove.
